## **1 INTRODUCTION AND BACKGROUND**

### **1.1 Document Overview**

The objective of this document is to provide the detail of technical design, deployment and configuration of different components of Mobile Application to Secure Tenure (MAST) application. It also provides configuration details of external third party tools that are utilized in MAST application framework.

### **1.2 Context for MAST**

The technology framework outlined in this document was developed to support the collection of land rights information using mobile technology and effectively storing information to create an inventory of land information that creates a greater degree of tenure security.

The Mobile Technology and Crowd sourcing to Strengthen Land Tenure Security Pilot (hereafter referred to as Mobile Application to Secure Tenure (MAST) is testing the viability of an innovative participatory or “crowdsourced approach” to capturing land rights information, including information about customary holdings, using mobile technologies.

The Cloudburst Group is implementing this project for the United States Agency for International Development (USAID). The MAST pilot is issued under the Evaluation, Research and Communication (ERC) contract, which focuses on Strengthening Tenure and Resource Rights. This contract is managed by USAID’s Washington-based Land Tenure and Resource Management Office. The MAST Pilot program fits into USAID’s strategic reform agenda pertaining to the use of science and technology to resolve development problems.

The development of the information technology platforms for the Mobile Application to Secure Tenure (MAST) has been implemented in Tanzania. The objectives of the Pilot are congruent with the needs of the Government of Tanzania related to helping to demarcate and secure land rights. Tanzanian development priorities are focused on lowering the cost of land titling programs and improving land governance in order to stimulate economic development, particularly by promoting large-scale investment in agriculture.

For the first phase of the pilot a relatively small village, Ilalasimba, was selected in Iringa Rural District. Iringa falls in the important Southern Agricultural Growth Corridor of Tanzania (SAGCOT), a zone of interest for both the Government of Tanzania and USAID. The Ilalasimba village is fairly representative of the average Tanzanian village. Most of the economic activities within the village are focused on agriculture. Maize is the predominant crop, and several secondary cash crops are grown by inhabitants (tomatoes, sunflower and tobacco). It has an estimated area of 31 sq. km and a small population (325 households). On average, each household occupies 2 or 3 parcels. Parcel sizes range from 5 to 10 acres and larger holdings are farmed in peripheral areas of the village.

### 1.3 Application Overview

The MAST application provides a suite of applications to support collection and management of land rights information with a mobile application to capture land rights information in the field and a back-end land rights data management infrastructure application with tools to manage an inventory of land information.

The initial pilot of MAST application has been implemented in Illalasimba, Iringa, Tanzania. The key components of MAST Framework are:

- **Mobile Data Capture Application** – Key component of MAST Framework is Android based Mobile application that is focused on the capture of land rights information (spatial, alphanumeric and multimedia). The Mobile application allows for the collection of data without being connected to a central cloud based server in offline mode. Data is collected and stored on users' handheld device, and once the user is within the influence region of the internet, data can be synced and sent back to the server.
- **Land Rights Data Management (Web) Application** – MAST data capture application is provided with a back-end web application which provides the facility to configure the mobile application, manage data collection projects, and manage land rights information data that has been collected in the field. Key modules of web application are:
  - Configuration Tool – The Web based configuration tool provides the facility to configure the land rights data collection mobile application. Configuration tool provides the facility to configure the attribute fields of data collection form that are collected in the field. This enables the land rights information survey exercise to be performed in multiple environments by configuring the data collection form for the specific needs of the area, for a specific project.
  - Administration Tool – The Administration tool provides the facility to manage users, roles; import and configure data layers; configure layer groups; configure survey projects; and configure master attributes that can be used in projects. This module facilitates in creation and configuration of survey projects, and the association of layer groups and users.
  - Data Management Infrastructure – The Data collected on mobile devices is transferred to a cloud based Data Management application, which provides tools to ingest, manage and store data of land rights information. It also provides mapping tool as well as reporting components so that required Land Rights reports can be generated.

Mobile Application to Capture Land Rights Information in Field for building a reliable inventory of land.

Web Application to ingest, manage and store data of land rights information and generate Land Rights reports.

## 2 OVERVIEW OF MAST APPLICATION SUITE

The MAST Application suite consists of following sub-systems to provide the requirements of Land Rights Data Capture, Configuration and Data Management functionalities.

1. Mobile Application to Secure Tenure
2. Land Rights Data Infrastructure Web Application
  - Administration Tool
  - Mobile Configuration Tool
  - Land Rights Data Management Tool

This section lists the functional overview of various components and tools of Mobile and Web Application, which describe the general functions of the MAST software system.

### 2.1 Workflow of Mobile Data Capture Application

The Mobile Application to Secure Tenure of the MAST application suite provides the facility to capture spatial, attribute and multimedia data in the field. Figure 1 depicts the high level workflow of the mobile application of the MAST System, along with the user interaction with the different components of the system.

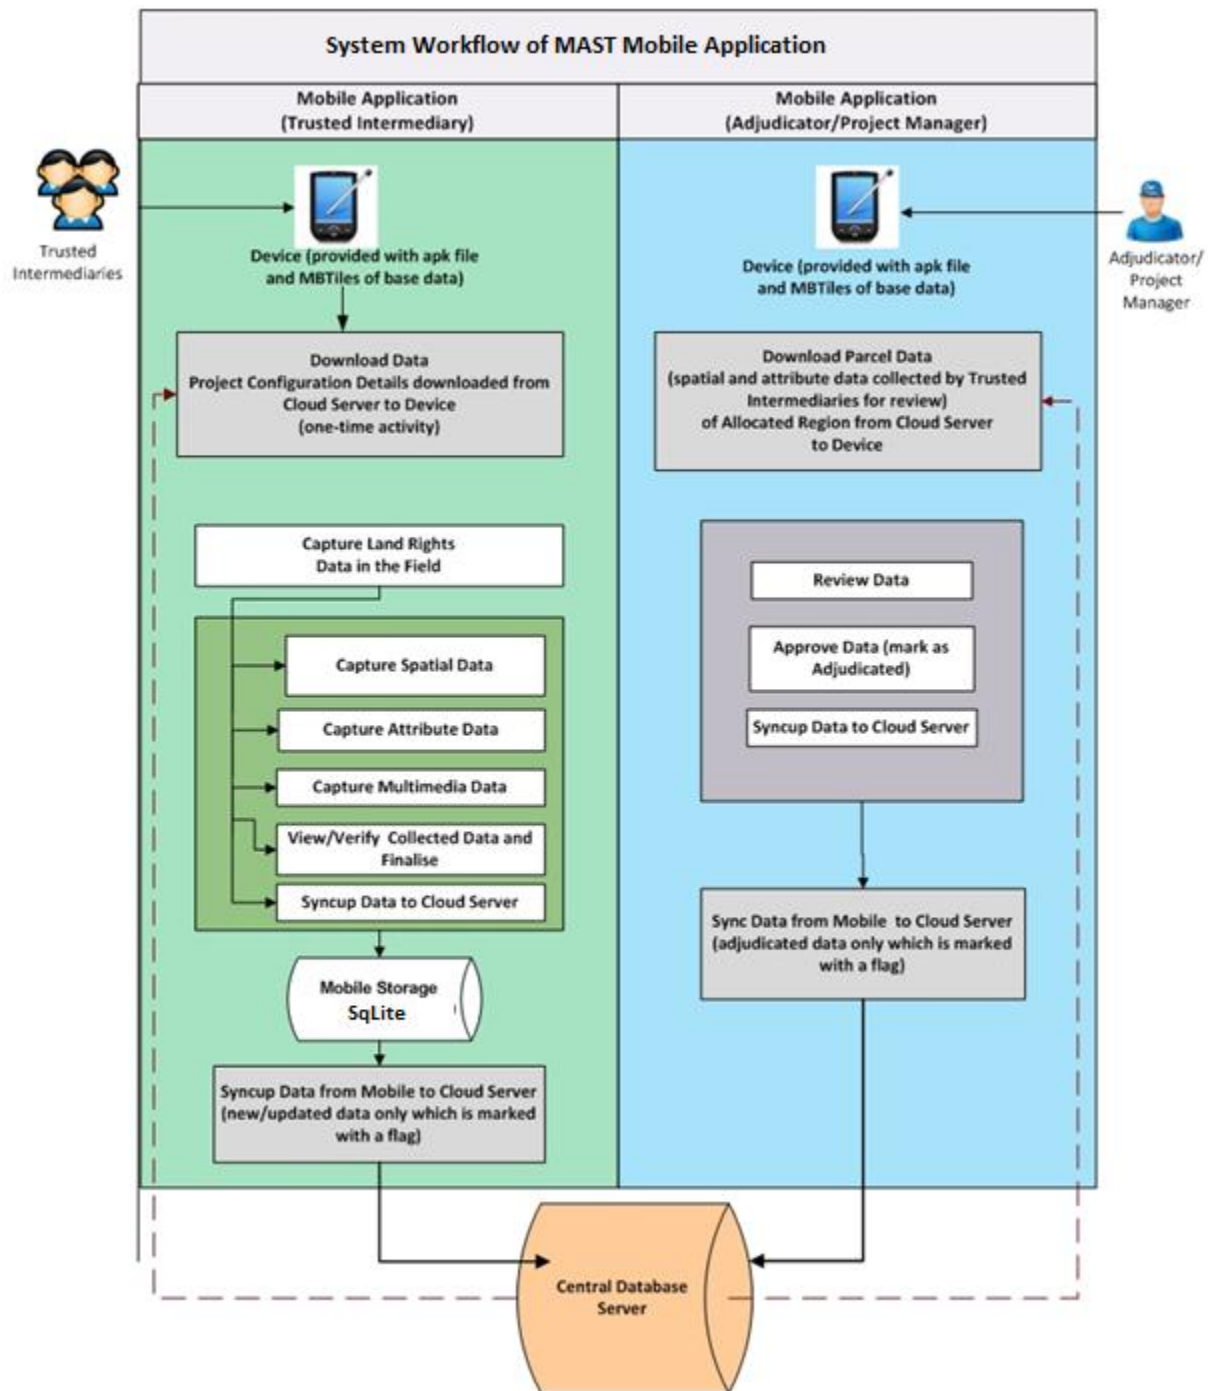

Figure 1: Workflow of Mobile Data Capture Application

Trusted Intermediaries or parasurveyors (individuals that are trained specifically to capture land rights information with the MAST application) will utilize the mobile data capture application to capture land rights information (consisting of spatial, attribute and multimedia data) of spatial units in field.

- Users will download the data has been configured for the project, before the initiation of data capture.
- Users will download the project configuration information (as a one-time activity) in the device before initiation of data capture process.
- User will also download the base data for allocated project as a onetime activity on mobile device.

The download of the data provides the basis for data capture. Once the data capture is completed, data will be synced to the back-end cloud server (automatically and also via a user initiated event of data sync up).

At this time, an adjudicator (authorized user with authority) will download the collected data on their device for review and adjudication. Using the mobile data capture application, he/she will be able to review and approve the data of spatial units collected by trusted intermediaries.

A Project Manager and other users can also utilize the same application for data review.

## 2.2 Workflow of Land Rights Data Infrastructure Web Application

The Web application of MAST System provides functionalities to manage the users and data layers, configure a data collection project and administer data that has been collected in the field. The following figure # depicts a workflow of web application starting from user creation to final generation of reports. It is configured so that different users will have access privileges to different components of web application as depicted in the workflow. A designated System Administrator will have access to all the components/features of web application.

Different functionalities provided in the web application are categorized into following modules which will be accessed by authorized users to manager survey project and data collected in the field and then generate reports/certificates on approved data:

- Administration Tool
- Mobile Configuration Tool
- Data Management Tool
- Reporting Tool

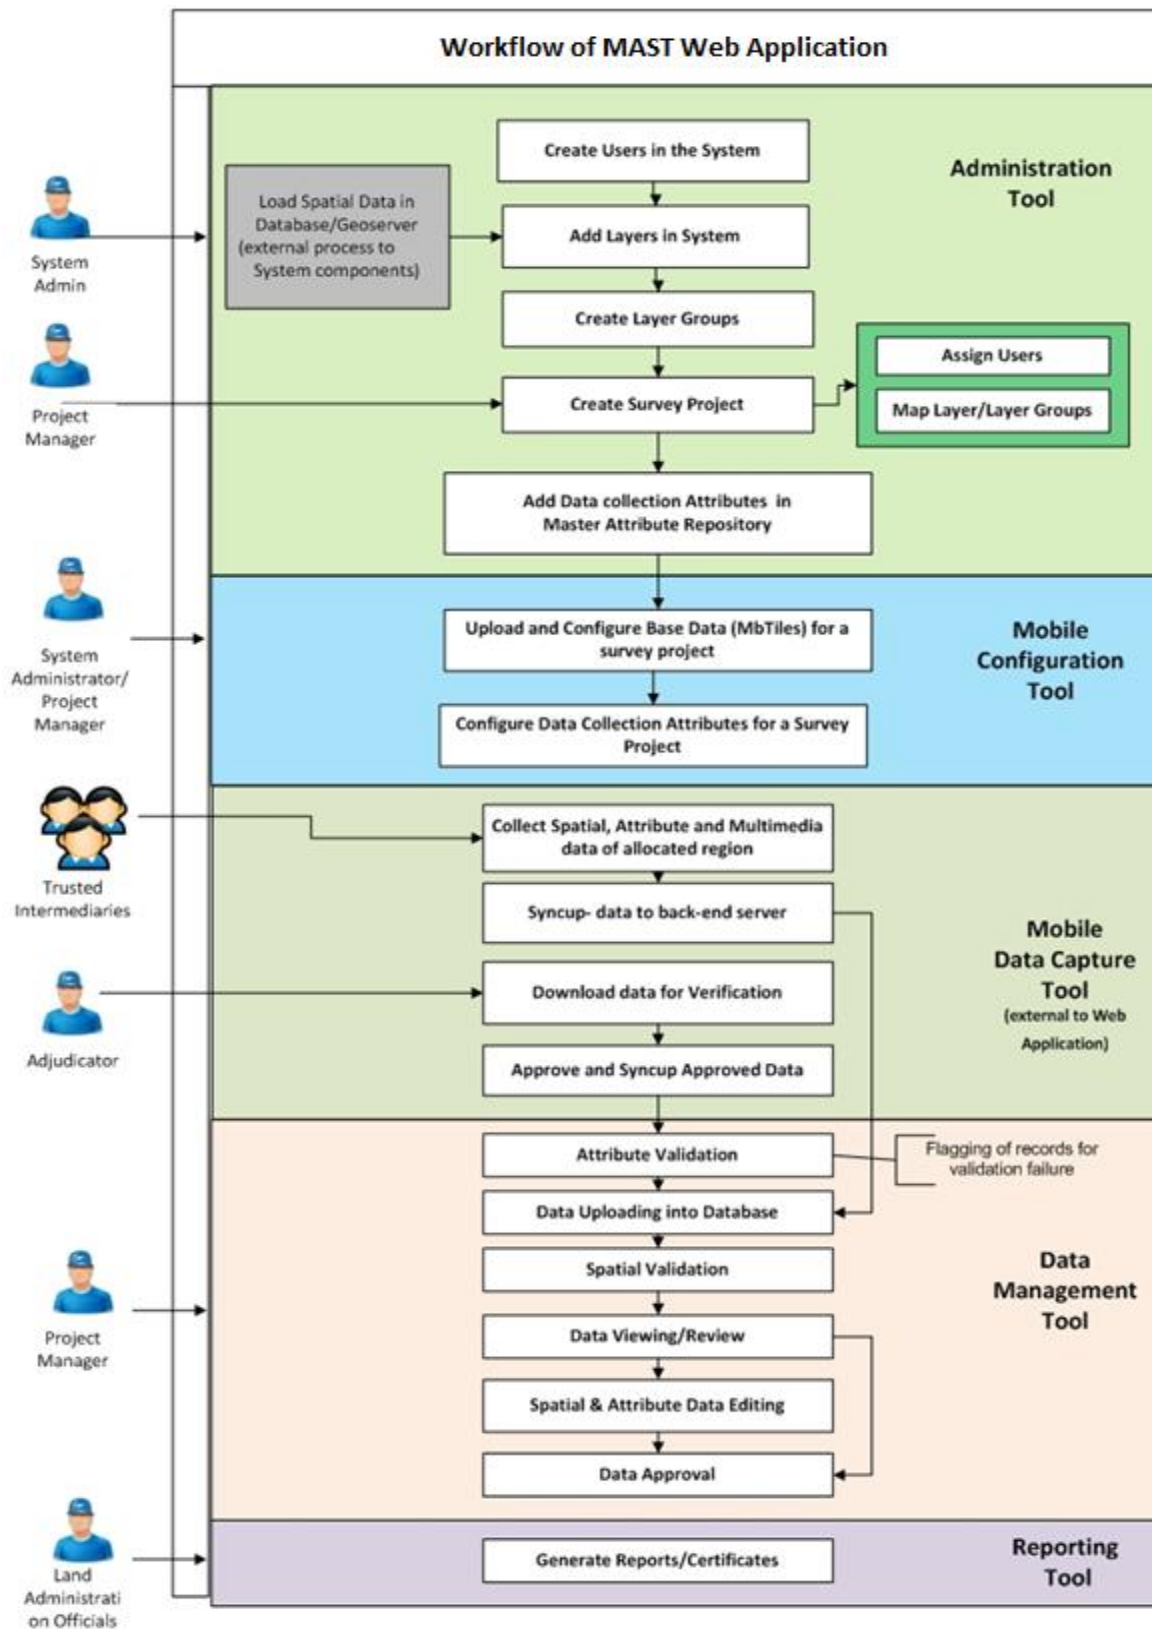

Figure 2: Workflow of Web based Data Infrastructure Application

- **Administration Tool** – This tool will be accessed by System Administrator to create and manage users who will be accessing the system. It will also provide facility to add/configure spatial data layers in the application, which have been loaded and configured in Geoserver. It will also facilitate the creation of layer groups.

Whenever a new data collection project is initiated, a new survey project is created in the System which will then be mapped to the users who will have permission to access and work on the survey project. Layers will also be configured in the survey project which will be accessible in the Data Management tool (which has a Map Viewer component) of web application when a specific project is accessed in it.

- **Master Attribute Repository** – The administration user will be able to manage the master data and configure data collection attributes. The user will have the ability to define custom attributes. Attributes which will be then mapped to different survey projects for data collection using the mobile configuration tool.
- **Mobile Configuration Tool** - Once the survey project is created in the system using Administration Tool, authorized user (Project Manager of the designed survey project) can configure the data that will be ported to the mobile application. The MAST Configuration Tool will provide the facility to:
  - Upload and configure base data layers (in the form of MbTiles) that will be downloaded by the mobile application users.
  - User can configure the data collection attributes which will be collected in the field in a specific survey project. User will need to select the desired attributes for a project from the master list of attributes.
- **Data Management Tool** – The MAST Web Application provides a data management tool which will be utilized once the data collection is collected in the field and data is synced back to the cloud-based (back-end) server. All the data that is synced by the mobile data capture application will be stored in the centralized database in the cloud-based server post sync-up. Using the Data management tool, authorized users will be able to validate, view, edit and approve the land rights data collected in the field.
  - Web Mapping Tool – Web mapping tools are a set of tools to perform basic to advanced functions based on user rights. These tools includes
    - Layer Manager – Enable/disable layer view, set transparency
    - Navigation Tools
    - Query builder
    - Spatial Editing
    - Attribute Editing
    - Export
    - Print
  - Reporting Tool – The Land Administration Officials will then utilize the reporting tool to generate reports/land rights certificates.

## 2.3 Functionality Role Matrix

This section provides an overview of the mapping of different functional roles in the system.

S.No	User Role	Group Name	Detail Description
1	System Administrator	Manager	<p>Super User is the administrator of the MAST Framework who will have full access permissions of all the functionalities of application including all data and will be in charge of system maintenance.</p> <p>They will be responsible for master data management, managing MAST projects, managing users and allocating roles and responsibilities to the users.</p> <p>System Administrator will also be able to configure data collection forms for specific survey projects.</p>
2	Trusted Intermediary	Data Collector	<p>Trusted Intermediaries will collect land rights data in the field using mobile devices. They will capture spatial, attribute and multimedia information of spatial units in the field. They will also verify the data before transferring the collected to backend Land Rights Data Management application.</p>
3	Adjudicator	Data Collector	<p>Adjudicator will utilize Mobile Data Capture application to review, approve and validate the collected data on the mobile device. They will download the data collected by Trusted Intermediaries from the back-end for verification and validation. After validation, they will upload the data to the MAST Data Management Application.</p>
4	Land Administration Official	Designated User	<p>These are government land officials in state agencies. They will access the Land Rights Data Management Application to view and print spatial data (maps) and produce reports that are required for the formalization of land rights. They will have full access of data for a designated survey project.</p>
5	Project Manager	Manager	<p>The Project Manager will have full access to entered data into the MAST database using Land Rights Data Management application and be able to review and edit data. He or she will have full permissions to add, delete, or modify data. The primary function will be to validate data that has been committed to the MAST database.</p>

### 3 ARCHITECTURE OF MAST

MAST Application suite consists of following sub-systems to provide the requirements of Land Rights Data Capture, Configuration and Data management functionalities.

- Mobile Application to Secure Tenure
- Land Rights Data Infrastructure Web Application

This section provides details of high level design and architecture of MAST mobile and web application.

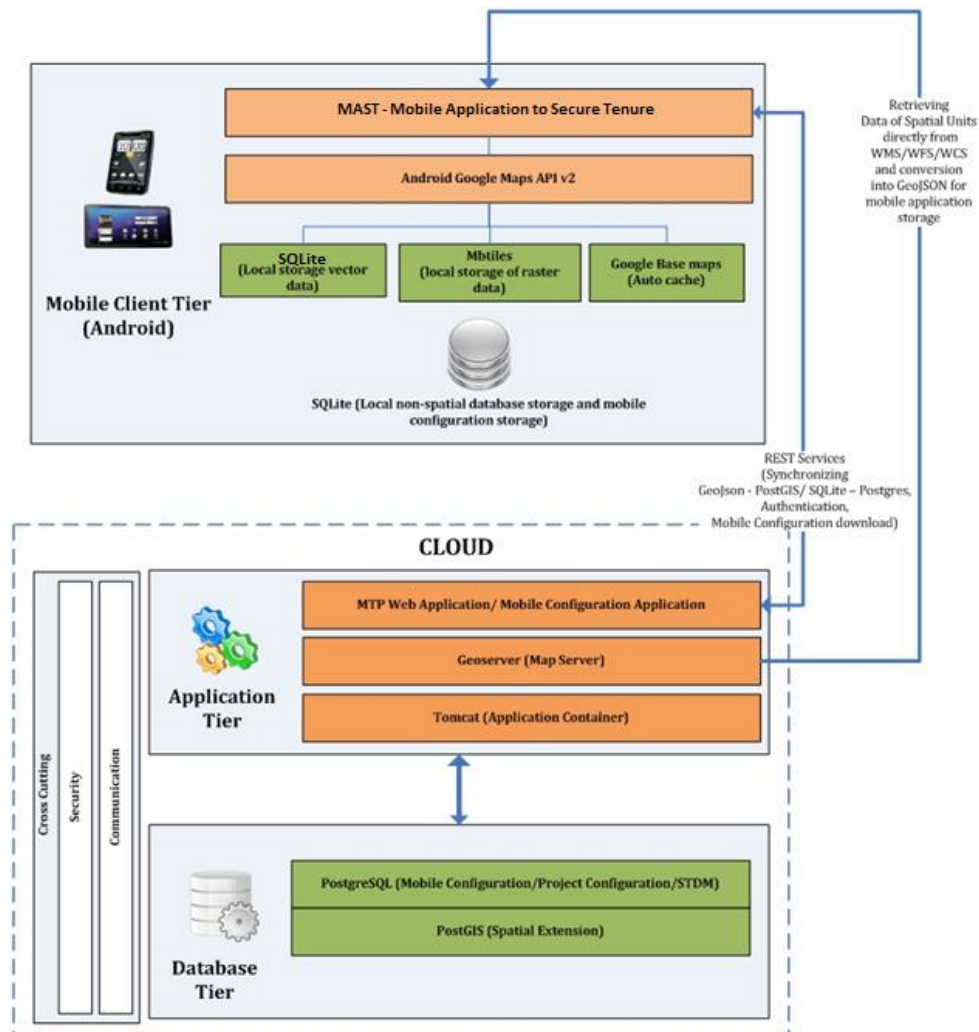

Figure 3: Conceptual Design of MAST Mobile Application Framework

### 3.1 Architecture of Mobile Data Capture Application

The MAST Mobile Data Capture framework consists of tools for offline spatial and textual data capturing and editing and connects to custom rest based services to download the mobile configuration data on mobile devices and allows for syncing of the collected data to the server. Spatial Editing and info functionalities are integrated into the using open source JTS library. Layer Manager is built to give user accessibility to toggle between layers. The MAST Mobile Data Capture framework also provides support for viewing application in multiple languages, customizing capture data features and changing colors of captured features according to the user preferences. It also provides accessibility to authenticate user using credentials created on the server for a specific project. This prevents any non-user using the application.

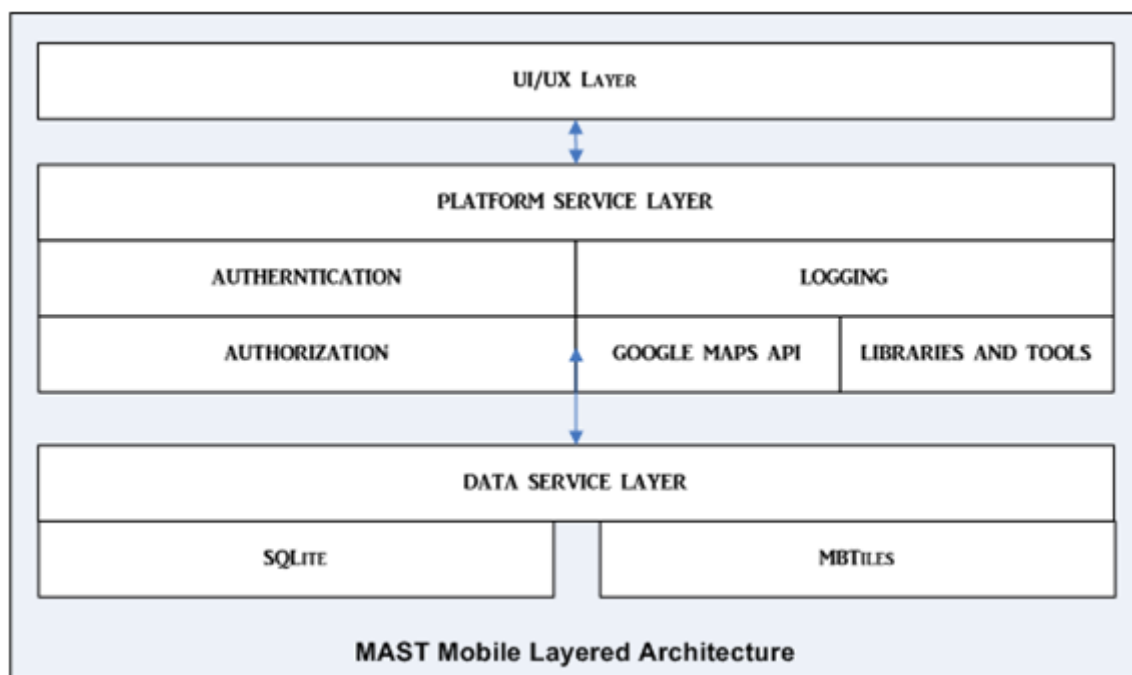

Figure 4: N-Tier architecture of MAST Mobile application

As shown in the figure above MAST mobile application can be broadly divided into three layers:

#### UI/UX Layer

UI Layer, which interacts with the user and is responsible for showing results and taking user inputs. A typical user interface of the application consists of action bar and the application content area. A UI is defined in an xml file. During compilation, each element in the XML is compiled into equivalent Android GUI class with attributes represented by methods.

### **Platform Service Layer**

Service Layer which is responsible for all the operations in the application and connects all three layers. Service layers are responsible to make calls to the rest services for authentication and authorization when online and saving the user details in Data service layer.

Platform service layer also uses the libraries and tools to perform business operations and Displaying maps using Google Map API for spatial layer display and manipulation in device.

Google Maps API is also used to show google satellite map and also offline maps using Tile overlays (in .mbtiles format) to ease in the data capture in remote locations with very poor internet connectivity. Geometry classes of Marker, Circle, Polyline and Polygon from the Google Maps API are used for showing features on the map.

### **Data Service Layer**

Data Service Layer deals with interacting with the underlying database and processing data requests originating from the service layer. Data service layer consists of read only mbtiles file and SQLite database in WKT format for easy read and write capabilities of geometries along with their attributes. All the form data is also stored in SQLite database for faster fetching and editing of data. The offline data is stored on the device in folders configured for the application.

All the above sub sections combined makes the MAST Mobile Data Capture Application which is wrapped in an .apk file using Android Software development kit (SDK) and Android development toolkit (ADT).

## **3.2 Architecture of Land Rights Data Infrastructure Web Application**

Implementation of web based application is based on open standards such as WMS, WFS, WCS from Open Geospatial Consortium implemented using GeoServer, PostgreSQL/PostGIS database for spatial database. It is flexible, reliable and scalable as the underlying architecture is based on stateless protocol using rest based services.

The solution utilizes web based n-tier architecture on Java2 Enterprise Edition (J2EE) platform and PostgreSQL/PostGIS Relational Database. The solution proposed consists of a centralized database server.

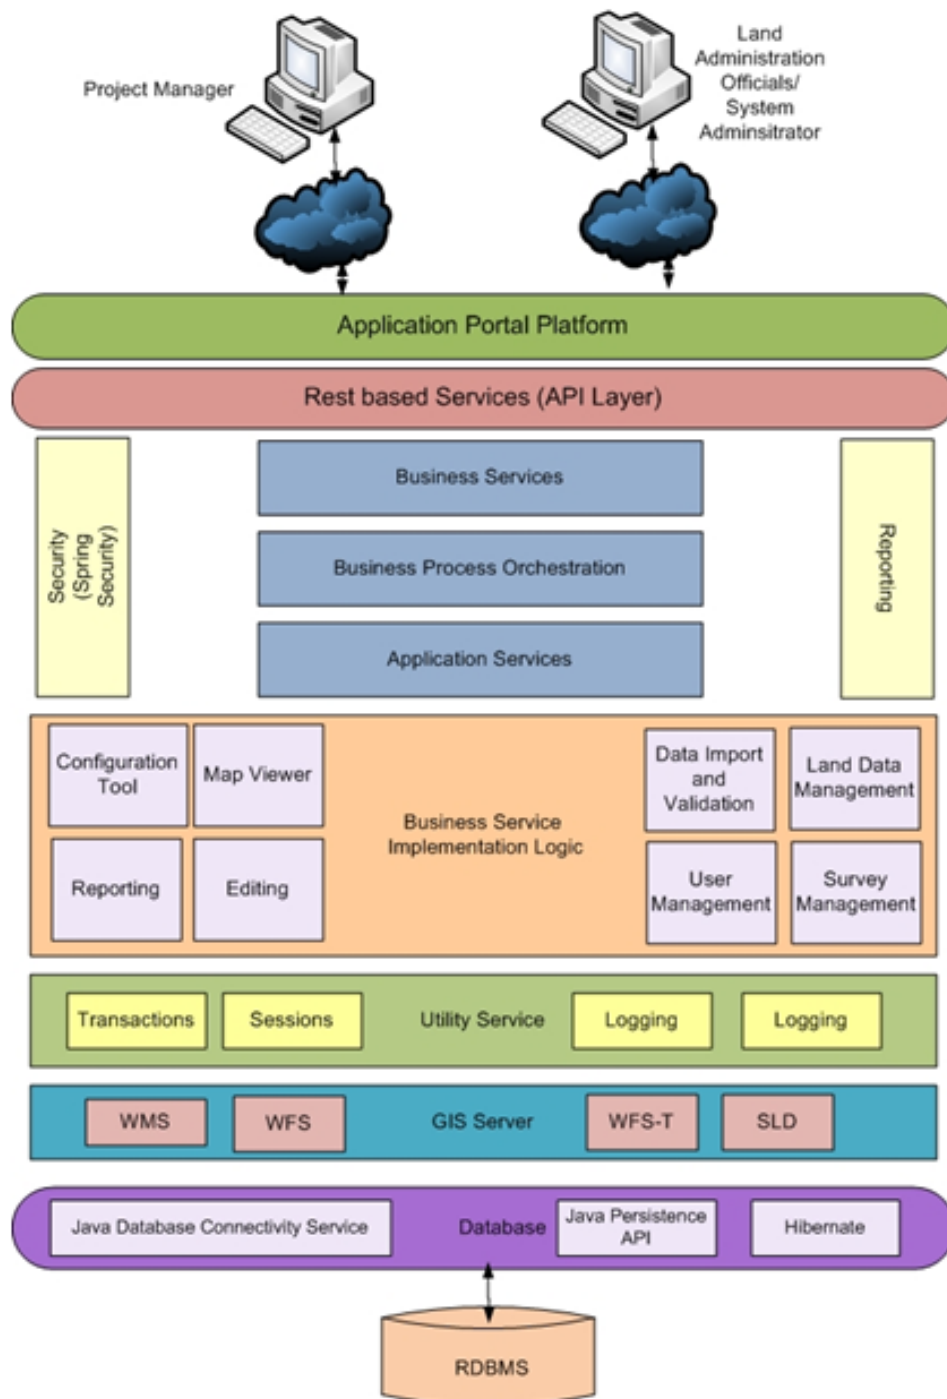

Figure 5: Multi-tier solution of WebGIS Application

MAST web application is developed as a Web GIS platform to manage, visualize and analyze spatial data through a standard web browser. MAST web application is purely based on OGC standards such as WMS, WFS and WPS and can use any OGC Compliant commercial or Open Source web mapping engines such as Geoserver.

**Presentation/ Web Tier:** It is the user interface which is responsible for gathering inputs from the user and passing the same to the business layer for processing. The presentation layer ensures that the communications passing through are in the appropriate form for the recipient business objects in the business tier. In the proposed system, the user interface constitutes this tier.

- This tier is based on XHTML/ CSS and interact with the business tier via a set of Java Server Pages and JavaScript Libraries.
- This interaction will leverage on the AJAX (Asynchronous JavaScript and XML) technology to give a seamless experience to the user. This will also enhance the response time as only the relevant dataset will be fetched from the server at any given time.
- This implementation is scalable, platform-independent and complies with the web standards.

**Service Layer:** Service layer implements service level requirement through which the solution achieves scalability, manageability, maintainability and extensibility. In MAST, the service layer allows following flexibility –

- Enables developer to make a clear distinction between web type activity best suited to be done in controller or a generic business logic that is not web-related.
- Enables testing of service enabled business logic separately from controller logic.
- Enables transactional behaviour, encompasses multiple data objects that should be part of same transaction.

**Business Tier:** The Business logic tier implements the business rules for the system, but it treats data as objects and is not concerned with how the data is stored or displayed. When the client tier requests some information, the business logic tier manages that request, deciding what information to retrieve and whether the client is entitled to that piece of information. When the client performs some action on a piece of information, such as updating a field, adding a new object, or deleting an object, again it is the responsibility of the business logic tier to decide whether the client is entitled to make the change, and making the change if so, in a manner that is consistent with the requirements of the system.

In MAST, two engines - mapping engine and data computation engine – constitute this tier.

- The Mapping Engine will interact with the Web Tier and the Database Tier through OGC-Compliant Web Mapping Service (WMS) and Web Feature Service (WFS). This ensures faster performance, interoperability between different systems and thus, unlimited scalability
- The Data Exchange Engine process the AJAX requests from the Web Tier and return the response from the Integration Tier back to the Web Tier. This engine will be custom built based on the requirements of the project.

**Data Access Layer:** The data access tier lives between the business logic tier and the data tier and handles the translation from data in its native format, such as SQL tables or XML elements, to a form more suitable for the business logic tier, such as objects. The integration tier is often referred to as a data abstraction layer because it allows the business logic tier to treat the data

in an abstract manner; that is, it can treat the data as objects without being concerned with the details of how the data is actually stored.

**Database Tier:** This consists of environment that allows persistence of the user information – both lookup and computed data. Physical implementation of this layer could be files on the system or databases.

This enables easy change of the data tier to a completely different database server application or from a database server to a set of XML files. If the data tier is changed, the only modification required will be in the integration tier and the rest of the application will work just as before without any modification.

Database tier consists of Hibernate an object relational mapping framework that maps the underlying PostgreSQL relational database. Database tier maps Java classes with underlying relational database tables with high level object handling functions.

MAST infrastructure uses PostgreSQL an open source RDMS as backend database. Spatial data is stored using PostGIS a spatial extension of PostgreSQL.

### 3.3 Overall Architectural Considerations

#### 3.3.1 Data Collection

MAST mobile application is used to collect data in offline mode. The spatial data is stored in the SQLite database in WKT format. The form data associated with a parcel is also stored in SQLite database. This storage method helps the device to work seamlessly in offline mode as fetching and editing the data is much faster as compared to parsing xml or GeoJson based storage techniques.

To ease in the data collection offline spatial data configured through web is stored in local storage and is fetched as tiles to give uninterrupted base map even with no internet connectivity.

#### 3.3.2 Data Management

##### 3.3.2.1 Data Loading

##### **MAST web infrastructure**

Variety of spatial data can be loaded to MAST web infrastructure by publishing them in Geoserver.

- Geoserver supports variety of Vector and raster data formats (refer data formats section).
- In Geoserver data can be published from either flat files like shape files or spatial tables from RDBMS like PostGIS, Oracle spatial or Microsoft sq server spatial.

- Since MAST web infrastructure is build over PostgreSQL/Postgis we would refer to the methodology adopted to load data to spatial table in PostGIS.
- PGADMIN module of PostgreSQL have a plugin ( PostGIS shapefile and DBF loader) to load shape file to load data to postgis table.
- Shape files can be directly stored in Geoserver Data folder and accessed for publishing.

### **MAST Mobile application**

MAST mobile application required MBtiles created from raster files to act as base layer for offline mode. MBTiles can be generated from raster images using Tilemill application from Mapbox. Once mbtiles are created they can copied to device using usb connection at defined location.

#### ***3.3.2.2 Data Formats***

#### **Data Management Infrastructure**

The MAST Web application supports multiple data formats and follow OGC standards. Data collected from the mobile device will be auto-synced to the back-end server which can then be viewed, edited and approved on the web application. The web application supports the following data formats:

- Attribute Data - PostgreSQL – Attribute data is stored in postgres rdbms tables.
- **Vector Data Sources**
  - PostGIS Database - Spatial data can be loaded to postgresQL database with postGIS extension in tables with geometry datatype columns. Data coordinate reference system should be defined for the specific table for proper usage.
  - PostGIS tables having geometry support can be published using Geoserver, and can be served as base layer in MAST web infrastructure.
  - Shapefile - ESRI(tm) Shapefiles (\*.shp) - ESRI shape files can be loaded in Geoserver data folder and then be published in Geoserver to be served as base layer in MAST web infrastructure.
  - Web Feature Server (NG) -Web feature server extension for geoserver can be used to publish data in local geoserver that have been already published in 3rd party servers.
- **Raster Data Sources**
  - ArcGrid - Arc Grid Coverage Format
  - GeoTIFF - Tagged Image File Format with Geographic information
  - MBTiles – MBTiles file format
  - WorldImage - A raster file accompanied by a spatial data file
  - Images with tfw, jgw can be published and used as base layer in MAST web infrastructure.

- Image Pyramids - Image pyramids can be created from a local desktop/Laptop using GDal library and can be copied to geoserver data folder in the server. These tiles can then be published in geoserver which in turn can be used as base raster tiles in MAST web infrastructure.

### 3.3.2.3 Data Export

The MAST Web infrastructure provides the functionality to export spatial data.

- A user can access the export or download available in toolbar.
- By clicking the toolbar, user has access to download data into 3 different formats.
- KML format and shape-zip format for GIS data and csv format for attribute data.

Users have several sub-options to export either complete data set, to select a sub set of features or select features in an area of interest.

### 3.3.3 Data Processing

#### 3.3.3.1 Data download & Configuration Base Data on Mobile Device

The MAST web infrastructure application will provide the functionality to configure the project attributes that will be collected for a specific survey project using the mobile data capture application in the field.

Whenever a new survey project is created in the system, the Project Manager/Admin user will configure the attributes which will be utilized in the mobile data capture application to collect land rights information in the field for that specific project. The Project Manager/Admin will also configure offline data to be used in the project in the mobile devices. Data Collection attributes and the associated information to the offline spatial data configured for a project are stored in the server database. While the offline spatial data in form of MBTiles is stored in the file system of the server.

The following figure depicts the workflow of the configuration process of a project with specific attributes that are selected and downloaded from the master repository (in cloud server).

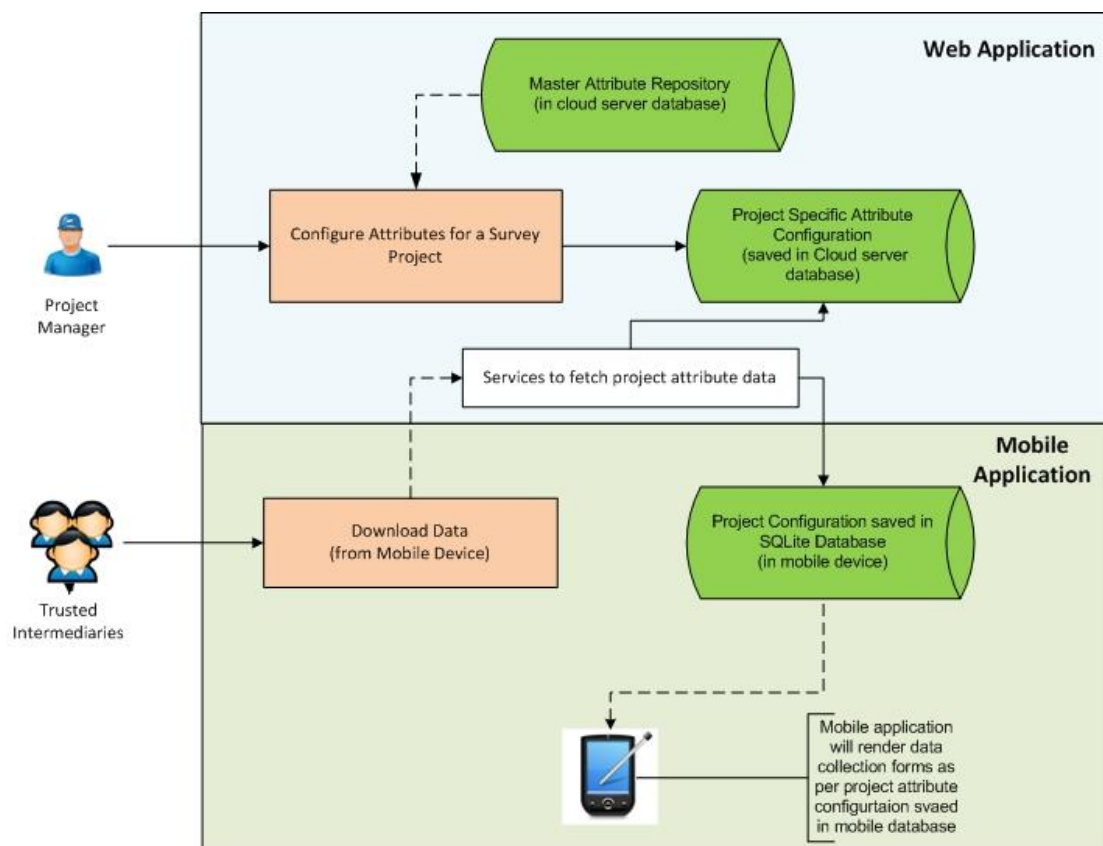

Figure 6: Project Specific Attribute Configuration and Data Transfer

When the mobile application user initiates data collection work, they will need to download the project configuration details by clicking on the download option in mobile application. The configured attributes will be fetched from the database server using REST services in JSON format and will be saved to SQLite database in mobile application. The configured offline data is downloaded using 'multipart/form-data' encoding type REST services.

Mobile application attribute pages are rendered according to the configuration saved in the mobile device for specific project. Concept of widgets is used to render dynamic forms in mobile devices according to the type of attributes (Boolean, numeric, text, dropdowns) and the offline data is shown in the layer manager.

Figure 8 below depicts the workflow process of base data download on the mobile device.

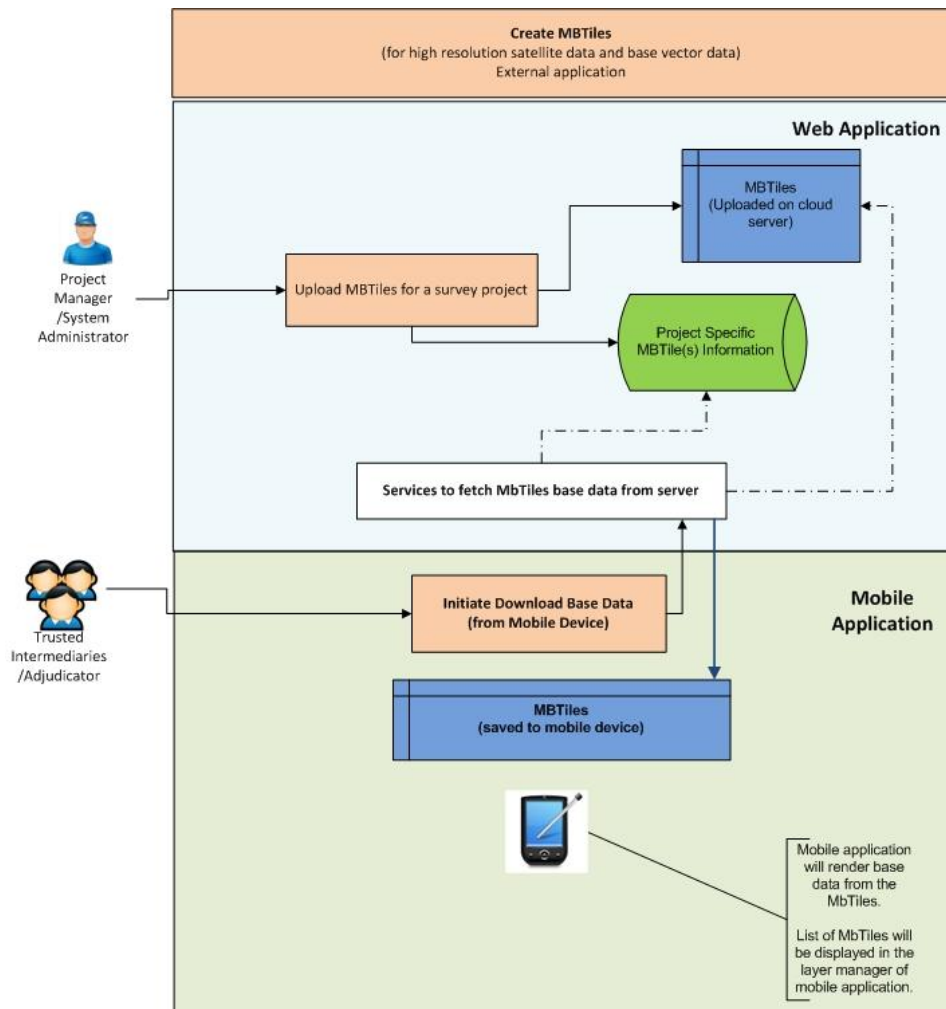

Figure 7: Base data Download on Mobile Ddevice

Other than the base data download, Google satellite data is also shown on mobile device which is auto-cached for the region displayed on the map first time when the internet connection is available and hence can be used subsequent times without internet connection.

### 3.3.3.2 MBTile Processing

This section provides the key steps involved in creation of MBTiles which needs to be pre-created for base data rendering on mobile device.

MapBox is used for the creation of MBTiles, which is a file format for storing map tiles in a single file. MBTiles allows us to render high resolution satellite imagery and vector data in a format that can be rendered in the mobile application irrespective of the size of the data as at a time only

few tiles are fetched which are to be displayed on the map, instead of the whole data as in conventional formats of spatial data storage.

Following flowchart depicts the process of creation of MBTiles, which is a one-time process done for each survey project.

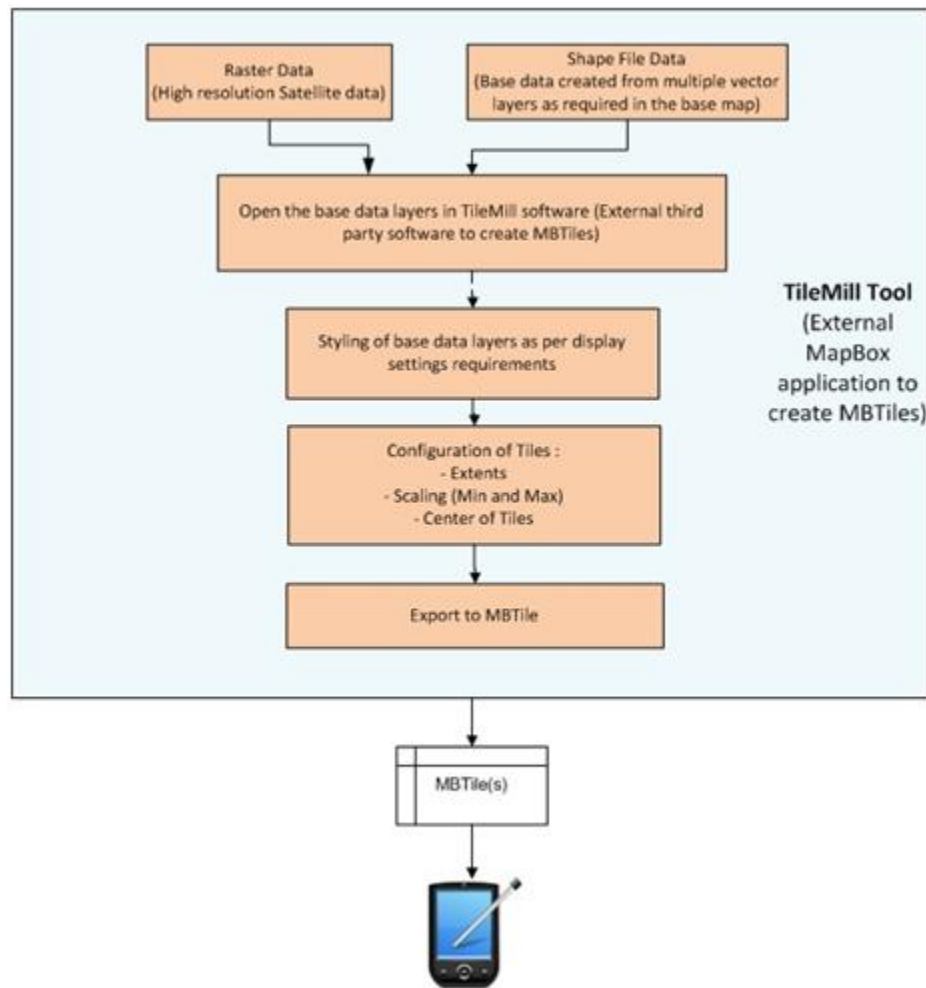

Figure 8: High level process workflow to create MBTiles (back ground layers on map device)

### 3.3.3.3 GIS mapping

The mapping function for MAST web infrastructure is implemented using a combination of technologies and protocols. The MAST web infrastructure is compliant with Open Geospatial Consortium (OGC). The client side features are developed using OpenLayers which makes it easy to put a dynamic map in any web page.

OpenLayers is a pure JavaScript library used for displaying map data in most modern web browsers, with no server-side dependencies. OpenLayers implements a JavaScript API for building rich web-based geographic applications. It interacts with Geoserver to show the GIS layers on the browser.

Navigation, spatial queries, and editing have been developed using a combination of features and functionalities available in OpenLayers client scripting and Geoserver rest services (i.e. WMS and WFS).

### 3.3.4 Reporting

The MAST web infrastructure reporting tool generates two types of reports Adjudication forms and CCRO reports.

Both these reports are currently hard coded into the system. These reports are generated by fetching data from backend database and rendered on a pre-formatted HTML page.

Map components for these reports are created from getmap call to Geoserver which returns image for the supplied extents. These images are then bound to the page to show parcel geometry in the report html img tag.

### 3.3.5 Security

#### 3.3.5.1 MAST Mobile Application

MAST mobile application works on the concept of one time authentication. This means that the user has to only authenticate first time it starts using the application. The first authentication is done from the server using authentication web service created on the server. Subsequently, the credentials are stored in the local database to ease in logging into the application.

#### 3.3.5.2 MAST Web Infrastructure

Application Security (Authentication and Authorization) - Security subsystem uses spring security framework to provide out of the box authentication and authorization against credentials stored in database which is configurable without changing application code. Based on authorization details received (role-based), the subsystem implicitly controls the access to the parts of the system by the user.

### 3.3.6 Platform

#### 3.3.6.1 Mobile Application

To get the best out of the MAST application, minimum configuration recommended for android devices are:

1. Android Version : Android 4.1 (Jelly Bean)
2. RAM : 1GB
3. Internal Storage : 32 GB
4. Camera : 2MP

5. Location capabilities : GPS+GLONASS
6. Battery : 2000 mAh

### 3.3.6.2 Web Application

#### Application Server

1. Linux based OS
2. RAM: 8GB
3. Processor : 8 core, 64 bit architecture
4. HDD : 500GB
5. Network speed : Moderate

#### Database Server

1. Linux based OS
2. RAM: 4GB
3. Processor : 4 core, 64 bit architecture
4. HDD : 100GB
5. Network speed : Moderate

### 3.3.7 Data Storage

#### 3.3.7.1 Data Storage/Rendering on Mobile Device

MAST uses base data on the mobile device. Base data will be provided in following forms to facilitate data collection on offline mode:

- Google base data (Auto-cached for specific region when the mobile is connected to the internet)
- High resolution satellite data (MBTiles needs to be created for high resolution base data)
- Vector base data (for roads and other layers) – MBTiles can be created for vector data layers which needs to be rendered in the mobile application as base data layers.

Figure 9: Data storage in mobile device (for data collection in offline mode)

Other than the base data that is loaded in configuration, the MAST mobile data capture application will manage spatial, alphanumeric and multimedia data of spatial units that are collected in the field; final data that is downloaded from the back-end server for data viewing/reviewing.

These data entities will be stored in the device in the following manner:

- Spatial data – Stored in SQLite database in WKT (Well known text) format.
- Alphanumeric data of spatial units – Stored in SQLite database in tabular structure.
- Multimedia Files – Stored in pre specified application folders in the mobile devices.

In Mobile devices MAST application configures storage of related data in a defined folder structure:

Parent folder: **MAST**

Sub-folders:

1. **Database** : contains sqlite database files
2. **Spatialdata** : all the offline .mbtiles files are stored in this folder
3. **Multimedia** : contains all the video/images captured using the MAST application.

### 3.3.8 System Performance

To get best performance from the application following have been kept in mind during the implementation of the system:

#### **Pure browser based HTML application**

System has been designed as a pure browser based HTML application that doesn't require plug-in download on browser.

#### **TMS and WMS-C cached map service**

Tile Map Service and WMS cache service has been used for quick generation of maps on browser.

#### **Optimizing data access**

MAST web infrastructure uses Java persistence API/hibernate ORM combination. Optimization of data access from database server is done by using Hibernate caching.

## 4 MAST SOLUTION INTEGRATION

### 4.1 MAST Technology Stack

The tables below provide a listing of development tools that have been used for the development MAST.

#### 4.1.1 Mobile Data Capture Application

Overall implementation of mobile application is based on following software tools listed below:

Software	Purpose	License/ Freeware	Details
Android Google Maps API v2	Android Application programming interface to develop map based application.	Open source	
Eclipse IDE (with Android Development Toolkit plugin)	Development Environment	Freeware	
MBTiles	Specification for storing tiled map data in SQLite databases	Open File format	MBTiles will be used to display Tiled Raster data on mobile device. These files will be pre-generated using an open source tools for high resolution Satellite images and other base data layers.
SQLite	SQL database Engine for local data storage	Open Source	Embedded SQL database engine in Mobile device for storage of attribute data of spatial units.
Android SDK API level 16 – Level21	Develop android native application	Open Source	

#### 4.1.2 Land Rights Data Management Web Application

Overall implementation of web application will be based on following software's as mentioned below:

Software	Purpose	License
Java/JEE	Programming Language/Development Platform	OpenSource

Apache Tomcat 7.x	Application Server for hosting the web application.	Open Source

### 4.2 MAST Solution Integration

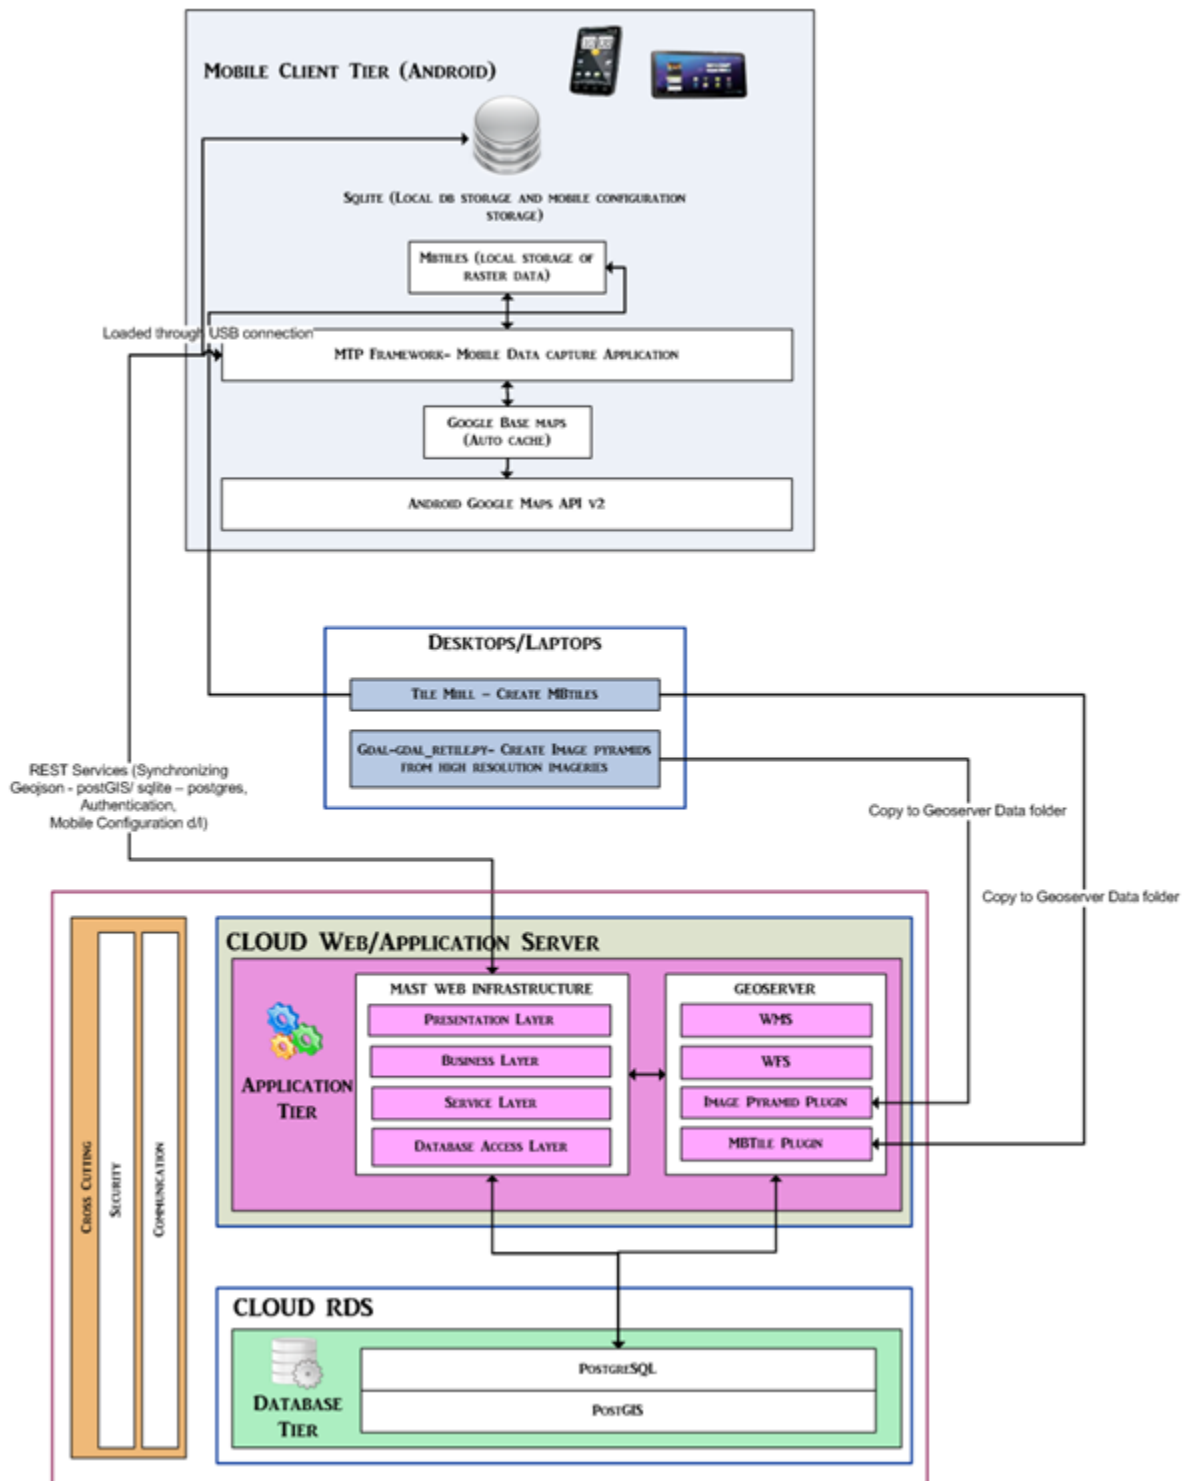

Figure 10: Overall Integration of MAST web infrastructure and Mobile application

Mast web infrastructure and mobile application consists of suite of web and mobile application and third part tools utilized for preprocessing of data.

Diagram in figure 7 depicts high level of integration between these components.

#### 4.2.1 Cloud Web Application Server

Cloud web application server and cloud Relational Database service are hosted in Amazon cloud environment.

- Application server contains Apache tomcat 7 web container installed in Ubuntu 14.04LTS OS.
- MAST web infrastructure and Geoserver web map server are hosted in this server inside Tomcat servlet container.
- Database configuration and connection pooling is managed by tomcat and the configurations are available in server.xml.

This server is hosted on public domain and calls are made on this server for the MAST web application to work with underlying calls to Geoserver to get spatial layers visible and MAST RDS server to get data from PostgreSQL/PostGIS database.

Geoserver would host the map layers including Vector and Raster layers. Geoserver is deployed in the Amazon Application server along with MAST web infrastructure.

#### 4.2.2 Cloud RDS

- Cloud RDS server hosts the relational database PostgreSQL/PostGIS.
- Calls are made on this server to get the data from MAST web infrastructure.
- MAST android application makes the rest call to Application server which in turn makes call to the RDS server to get spatial and non spatial data.

#### 4.2.3 Client Tier (MAST Android Mobile Application)

- Android MAST application is a native application that synchronizes data by using rest based services available in MAST web infrastructure.
- Native application stores the data in sqlite for local device.
- MB tiles can be downloaded from the MAST web infrastructure as configured with the Survey project or it can be copied to the device using USB connection.

#### 4.2.4 External Data Preprocessing

- MBTiles are created for high resolution satellite images as well as Vectors layer to be displayed as base layers in MAST android application. Mapbox tool Tilemill is used to create MB tile. MBtiles are created to be used in MAST mobile application as base layer for offline data capturing.
- Image Pyramid is created using GDALutility retile.py which is a python script that is used to create image tiles. This tool splits the larger images to smaller chunks that can be easily displayed on a web application with better performance.

Once pyramids are created they should be copied into Geoserver data folder to be published and used in MAST web infrastructure.

## 4.3 Configuration and Deployment

This section briefly describes the operational hardware requirement, network requirements and data transfer requirements for optimum performance of MAST web infrastructure application. It also covers lists of prerequisites and their installation, steps to deploy MAST web infrastructure WAR (web application archive) and server.xml configuration in Apache Tomcat for connecting to RDS server with connection pooling parameters.

### 4.3.1 Operational Requirement

#### **Application Instance**

Instance Type	:	m3 large
Processor Architecture	:	64Bit
vCPU	:	2
ECU	:	6.5
Memory GiB (RAM)	:	7.5
Instance Storage	:	1 x 32 SSD*6
Network Performance	:	Moderate

#### **RDS Instance**

Instance Type	:	m3 medium
Processor Architecture	:	64Bit
vCPU	:	1
ECU	:	3
Memory GiB (RAM)	:	3.75
Instance Storage	:	1 x 4 SSD*6
Network Performance	:	Moderate

#### **Amazon EBS Volume**

No of EBS Volumes	:	1
-------------------	---	---

Volume Type	:	Standard
Storage	:	250GB

### **Data Transfer In/out**

100GiB/100GiB

### **4.3.2 Deployment of Prerequisites & MAST**

This section will give a brief introduction on the installation, deployment and configuration of MAST web infrastructure and Geoserver on to a Linux based (Ubuntu) server. (Please refer to installation guide **MAST\_development\_environment\_installation\_setup\_guide\_RMSI\_final** for directions on loading prerequisites)

#### **4.3.2.1 MAST Deployment Prerequisites**

Core tools/applications used to deploy MAST web infrastructure and Geoserver on to Ubuntu 14.04 LTS are :

- JavaJDK 7 (64-bit)– Java Developer Kit
- PostgreSQL 9.3 (64-bit)
- PostGIS 2.1
- Tomcat 7 (64-bit)

### **Installing JavaJDK 7**

Java JDK 7 can be either be manually installed or can be installed from Ubuntu repository using command in Ubuntu Terminal:

```
$sudo add-apt-repository ppa:webupd8team/java
```

### **Installing PostgreSQL**

Ubuntu's default repositories contain PostgreSQL packages. We can then get the Postgres package and a "contrib" package that adds some additional utilities and functionality by using following command on Ubuntu Terminal:

```
$sudo apt-get update
$sudo apt-get install postgresql postgresql-contrib
```

### **Installing PostGIS**

As mentioned above PostGIS is available in Ubuntu's default repository. We can get install PostGIS by using following command on Ubuntu Terminal:

```
$sudo apt-get install postgresql-9.3-postgis
```

## Install Tomcat 7

Download Apache Tomcat 7 Server for Linux from <http://tomcat.apache.org/download-70.cgi>  
User below command in terminal to extract the tar file to tmp folder

```
$tar xvfz apache-tomcat*.tar.gz -C /tmp/
```

Move the extracted folder to usr folder after providing proper rights

```
$sudo su -c "chmod -R root:root /tmp/apache-tomcat*"
$mv /tmp/apache-tomcat-7 /usr/lib
```

Commands to Start and Stop the Tomcat Server

```
Start
/usr/lib/apache-tomcat-7/bin/startup.sh
Stop
/usr/lib/apache-tomcat-7/bin/shutdown.sh
```

## Pre-requisites

You will require administration privileges on your computer to complete this exercise.

### 4.3.2.2 MAST Web infrastructure/Geoserver Deployment

After all above installations are done, we are now ready to deploy MAST web Infrastructure and Geoserver in Tomcat.

Stop the Tomcat Server.

Copy MAST.war and Geoserver.war file to folder /usr/lib/apache-tomcat-7/webapps

Go to folder /usr/lib/apache-tomcat-7/conf folder

Open file server.xml file in edit mode and modify resource type tag to add rds server details and credentials.

```
<Resource type="javax.sql.DataSource"
    name="jdbc/Cloudburst"
    factory="org.apache.tomcat.jdbc.pool.DataSourceFactory"
    driverClassName="org.postgresql.Driver"
    url="jdbc:postgresql:hostname:port/database"
    username="username"
    password="password"

    testWhileIdle="true"
    testOnBorrow="true"
    testOnReturn="false"
    validationQuery="SELECT 1"
    validationInterval="30000"
    timeBetweenEvictionRunsMillis="5000"
```

```
maxActive="100"
minIdle="10"
maxWait="10000"
initialSize="10"
removeAbandonedTimeout="60"
removeAbandoned="true"
logAbandoned="true"
minEvictableIdleTimeMillis="30000"
jmxEnabled="true"
jdbcInterceptors="org.apache.tomcat.jdbc.pool.interceptor.ConnectionState;
org.apache.tomcat.jdbc.pool.interceptor.StatementFinalizer;
org.apache.tomcat.jdbc.pool.interceptor.SlowQueryReportJmx(threshold=10000)"
/>
```

Save server.xml file.

Start the Tomcat Server.

## Check deployment

User need to check whether Tomcat, MAST web infrastructure and Geoserver are deployed properly. For this user have to open any web browser and type the below urls to see whether home pages are loaded properly or not.

Tomcat: <http://appserverIP:8080/>

Web MAST Infrastructure: <http://appserverIP:8080/mast/>

Geoserver: <http://appserverIP:8080/geoserver>

### 4.3.3 Deployment on Amazon Architecture

Below mentioned details pertains to deployment done in Amazon Cloud AWS and RDS.

- Operating system used for Pilot deployment is Ubuntu 14.04LTS.
- Amazon Web Services (AWS) is used for hosting MAST web infrastructure. Amazon provides highly available and highly scalable platforms on Cloud.

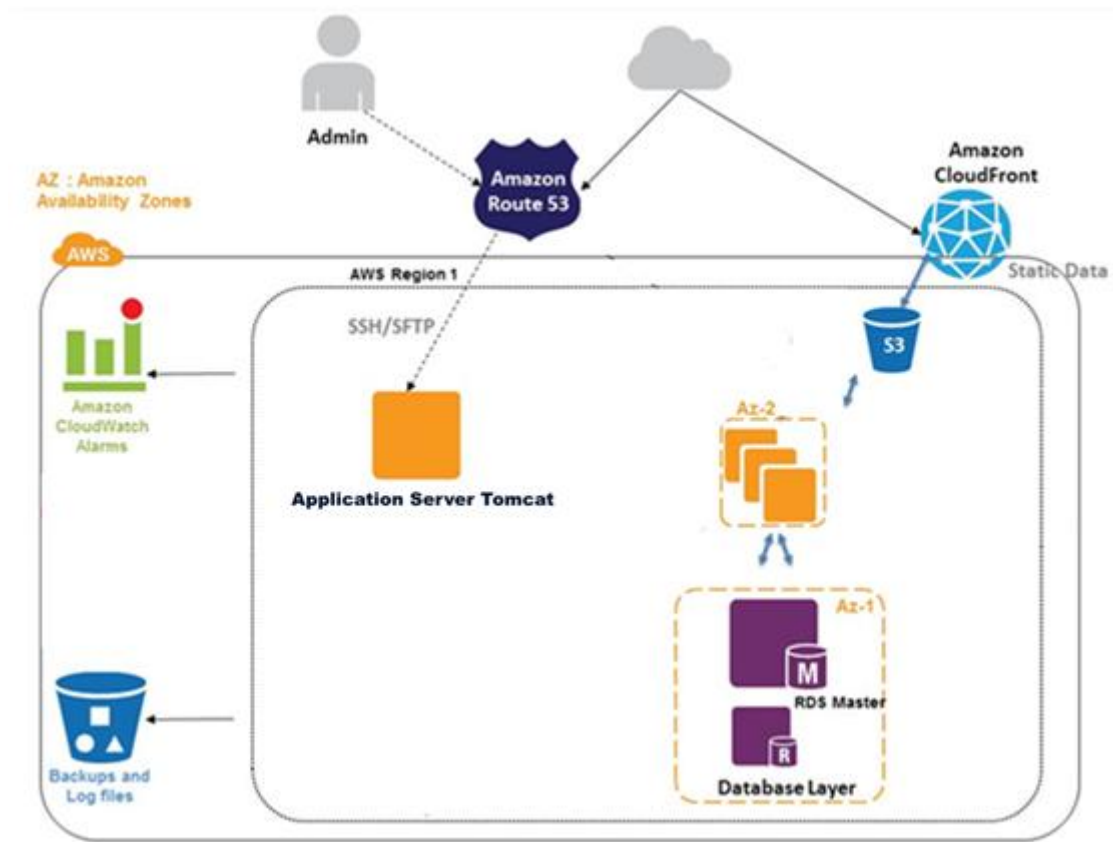

Figure 11: MAST web infrastructure Hosting

In the above diagram Application Server is used to deploy MAST web infrastructure and Geoserver in Apache Tomcat application container. RDS master server stores the PostgreSQL database with PostGIS extension for storing spatial and textual data.

Amazon Web Services provides the reliable, scalable, secure, and high performance infrastructure required for web applications while enabling an elastic, scale-out and scale-down infrastructure to match IT costs in real time as customer traffic fluctuates.

## 5.1 MAST Framework (PostgreSQL/PostGIS)

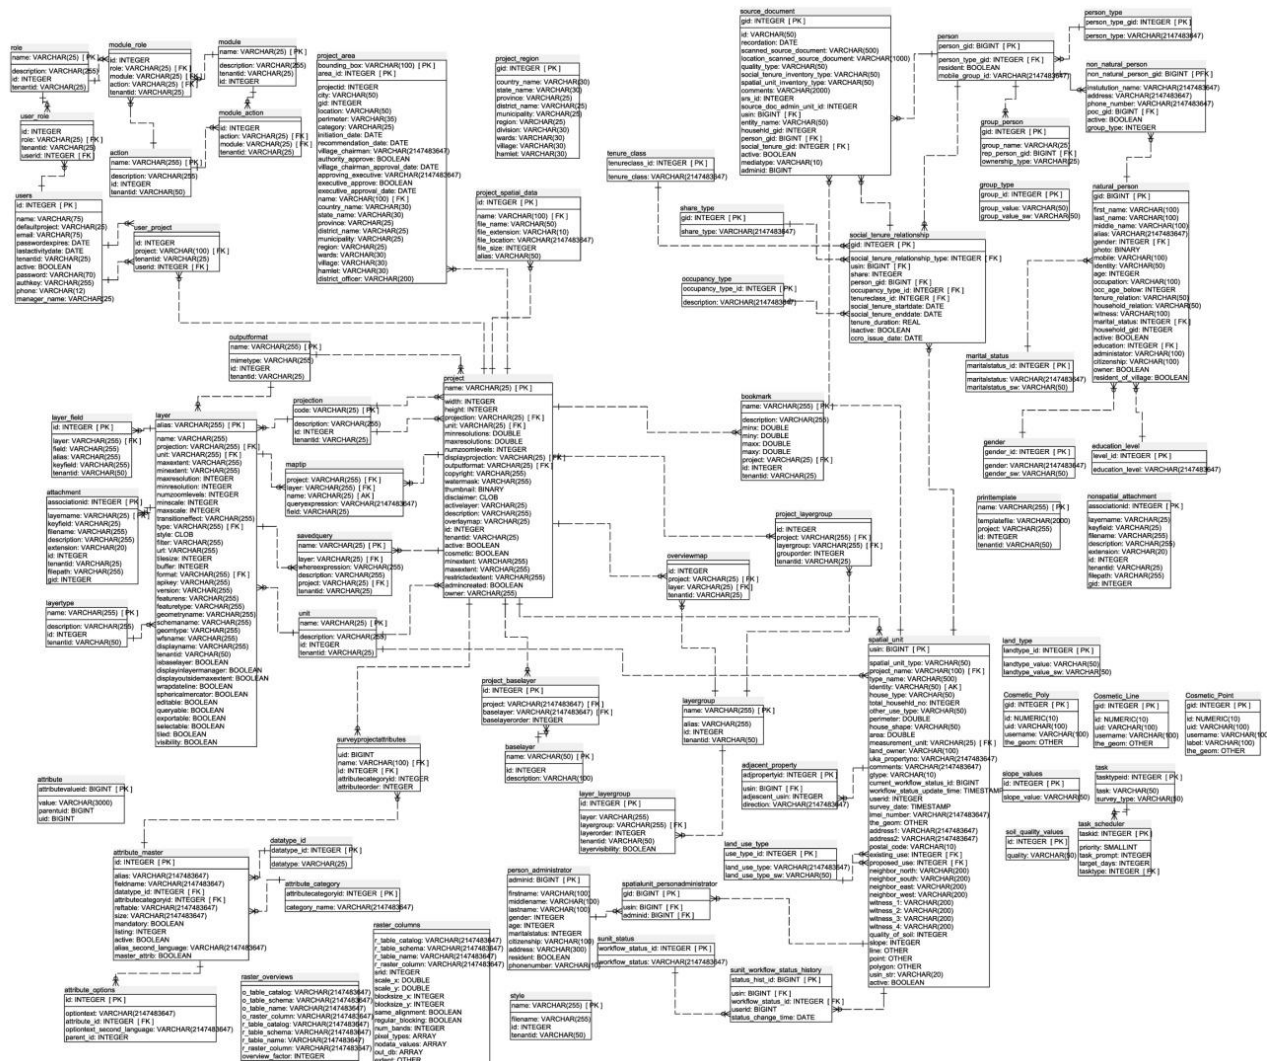

Figure 12: ER Diagram- MAST Web Infrastructure

## 5.1.1 Table Details

### 5.1.1.1 *action*

(Physical Name: action)

Logical Column Name	Physical Column Name	Type	PK	Nullable
name (PK)	name	VARCHAR(255)	PK	NOT NULL
description	description	VARCHAR(255)		
id	id	INTEGER		NOT NULL
tenantid	tenantid	VARCHAR(50)		

Referenced By

[module\\_action](#) referencing (name)

[module\\_role](#) referencing (name)

### 5.1.1.2 *adjacent\_property*

(Physical Name: adjacent\_property)

Logical Column Name	Physical Column Name	Type	PK	Nullable
adjpropertyid (PK)	adjpropertyid	INTEGER	PK	NOT NULL
usin ( <a href="#">FK</a> )	usin	BIGINT		NOT NULL
adjescent_usin	adjescent_usin	INTEGER		NOT NULL
direction	direction	VARCHAR(2147483647)		NOT NULL

References

[spatial\\_unit](#) through (usin)

#### 5.1.1.3 *attachment*

(Physical Name: attachment)

Logical Column Name	Physical Column Name	Type	PK	Nullable
associationid (PK)	associationid	INTEGER	PK	NOT NULL
layername ( <a href="#">FK</a> )	layername	VARCHAR(25)		NOT NULL
keyfield	keyfield	VARCHAR(25)		NOT NULL
filename	filename	VARCHAR(255)		
description	description	VARCHAR(255)		
extension	extension	VARCHAR(20)		
id	id	INTEGER		NOT NULL
tenantid	tenantid	VARCHAR(25)		
filepath	filepath	VARCHAR(255)		NOT NULL
gid	gid	INTEGER		NOT NULL

References

[layer](#) through (layername)

#### 5.1.1.4 *attribute*

(Physical Name: attribute)

Logical Column Name	Physical Column Name	Type	PK	Nullable
attributevalueid (PK)	attributevalueid	BIGINT	PK	NOT NULL
value	value	VARCHAR(3000)		NOT NULL
parentuid	parentuid	BIGINT		
uid	uid	BIGINT		NOT NULL

#### 5.1.1.5 *attribute\_category*

(Physical Name: attribute\_category)

1. General
  2. Person
  3. Tenure
  4. Multimedia
- etc

Logical Column Name	Physical Column Name	Type	PK	Nullable
attributecategoryid (PK)	attributecategoryid	INTEGER	PK	NOT NULL
category_name	category_name	VARCHAR(2147483647)		NOT NULL

Referenced By

[attribute\\_master](#) referencing (attributecategoryid)

#### 5.1.1.6 *attribute\_master*

(Physical Name: attribute\_master)

Stores all the attributes for lookup purpose

Logical Column Name	Physical Column Name	Type	PK	Nullable
id (PK)	id	INTEGER	PK	NOT NULL
primary key				
alias	alias	VARCHAR(2147483647)		NOT NULL
Display name				
fieldname	fieldname	VARCHAR(2147483647)		NOT NULL
actual field name				
datatype_id ( <a href="#">FK</a> )	datatype_id	INTEGER		NOT NULL
attributecategoryid ( <a href="#">FK</a> )	attributecategoryid	INTEGER		NOT NULL
reftable	reftable	VARCHAR(2147483647)		NOT NULL
Stores the actual table name that the attribute extends				
size	size	VARCHAR(2147483647)		NOT NULL
mandatory	mandatory	BOOLEAN		NOT NULL
true of the attribute refers to standard tables
